Why Focus on Adolescents?
Malnutrition during adolescence can have lifelong consequences. Adolescents undergo rapid biological and socioemotional changes and set lifelong dietary and related habits. Gender norms can leave girls disproportionately impacted by food insecurity, but many adolescent boys are malnourished as well. Adolescent girls are at risk of dropping out of school, marrying, and becoming pregnant—all of which can harm their nutrition and health as well as that of their offspring. Moreover, adolescence marks the last window of opportunity to reverse stunting.

Adolescent Nutrition in Bangladesh
• A nutrition transition is occurring, but undernutrition is still common among adolescents: Stunting has declined but remains high, thinness has remained steady, and overweight is increasing. Anemia and deficiencies in iodine, zinc, and vitamin A are common.

• Adolescents—especially girls in poorer households—consume inadequately diverse diets.

• Other determinants of poor nutrition include early marriage, which is declining but still common, and low secondary school enrollment, which is widespread.

• Within Bangladesh, there is large regional variation in different forms of malnutrition and their determinants.

• While there is less nutritional data on adolescent boys, they also experience a high burden of malnutrition, especially thinness.
Nutritional Status and Trends

**Anthropometry** in adolescent girls 10-18 years

- **Stunting**
  - 2011: 32%
  - 2012: 30%
  - 2013: 29%
  - 2014: 26%

- **Thinness**
  - 2011: 3%
  - 2012: 4%
  - 2013: 5%
  - 2014: 7%

- **Overweight or obesity**
  - 2011: 12%
  - 2012: 11%
  - 2013: 12%
  - 2014: 11%

Overweight and obesity, which are risk factors for diet-related noncommunicable diseases such as diabetes and cardiovascular disease, are rising in Bangladesh, as they are worldwide.

**Prevalence of thinness in adolescent girls 10–18 years by division in 2014**

Thinness—indicating acute deficiency in macronutrients, chronic undernutrition, or both—appears relatively low. This is because the standard measure of this indicator for adolescents uses a cutoff reflecting a severe level of thinness. If a cutoff that better corresponded with the severity of adult thinness were used, the prevalence of thinness would probably be closer to that of stunting.

**Prevalence of micronutrient deficiencies and anemia in 2011–2012**

- **Iodine**
  - 2011: 40%
  - 2012: 57%
  - 2013: 26%
- **Zinc**
  - 2011: 42%
  - 2012: 21%
  - 2013: 6%
- **Vitamin A**
  - 2011: 20%
  - 2012: 6%
  - 2013: 26%

Severe vitamin A deficiency (as shown in the graph) is relatively low, but marginal deficiency is much higher—74% in children 6–14 years and 40% in nonpregnant, nonlactating women.

**Prevalence of stunting in adolescent girls 10–18 years by division in 2014**

Stunting, which reflects past and recent chronic undernutrition, is declining among adolescent girls but remains high.

Stunting, which reflects past and recent chronic undernutrition, is declining among adolescent girls but remains high.
Prevalence of **inadequate dietary diversity** in women and adolescent girls 10–49 years in 2014

**By wealth quintile**

![Chart showing dietary diversity by wealth quintile](chart)

**By division**

![Map showing dietary diversity by division](map)

Note: Inadequate dietary diversity is defined here as consumption of fewer than 5 out of the 9 food groups in the previous 24 hours.

**Dietary intake**

More than half of adolescent girls and women consumed inadequately diverse diets nationally in 2014.

About 80% of kilocalories per capita per day in Bangladesh are from very micronutrient-poor foods, and 70% are from rice alone (75% for rural adolescents).

Only 58% of households have adequately iodized salt.

Dietary diversity varies by season: it is lowest during the post-aus season and highest during the monsoon.

**Diets of school-going adolescent boys and girls 13–17 years**

![Bar chart showing dietary habits](chart)

- Experienced hunger sometimes, often, or always in the past month: Boys 52%, Girls 57%
- Consumed fruit less than once per day: Boys 50%, Girls 50%
- Consumed vegetables less than once per day: Boys 26%, Girls 24%
- Drank carbonated soft drinks at least once per day: Boys 47%, Girls 47%
- Consumed fast food at least once per week: Boys 56%, Girls 47%
Key Determinants of Adolescent Malnutrition

**Child marriage and school attendance**

Delaying marriage by 1 year in Bangladesh has been associated with nearly a quarter-of-a-year increase in schooling as well as increased literacy for adolescent girls. Educational attainment is associated with a host of nutritional outcomes.

**Percentage of adolescents attending secondary school by division in 2014**

**Median age at first marriage among women 20–49 years by division in 2014**

**What Can Be Done?**

- Carry out interventions to promote safe and healthy diets rich in micronutrients and fiber, including fruits and vegetables, legumes, fish, eggs, meats, and dairy, and that aim to reduce consumption of energy-dense, nutrient-poor foods, such as sugar, refined flours, and oils.
- Expand programs that incentivize school enrollment, delay marriage, and increase educational attainment, especially for adolescents in the poorest households.
- Increase coverage of fortified rice, salt, oil, and wheat flour.
